Largest Study of its Kind of Women in Labor Finds Nitrous Oxide Safe, Side Effects Rare and Converting to Other Pain Management Techniques Differs by a Woman's Prior Birth History

Women in labor who had a prior vaginal birth had low rates of converting to other pain management techniques such as epidural or opioids

AURORA, Colo. (May 29, 2020) – Researchers at the University of Colorado College of Nursing and the School of Medicine Department of Anesthesiology at the Anschutz Medical Campus found that the use of nitrous oxide (N₂O) as a pain relief option for individuals in labor is safe for newborn children and laboring individual, and converting to a different form of pain relief such as an epidural or opioid is influenced by a woman's prior birth history and other factors.

The study, out today in *Journal of Midwifery & Women's Health*, surveyed 463 women who used nitrous oxide during labor. The study is the largest and first of its kind in the United States to report rates of side effects from N₂O use during labor, as well as reasons for women in labor after cesarean to convert to other forms of pain relief. Of the women who began using N₂O as an initial pain relief technique, 31% used only N₂O throughout labor and 69% transitioned to another pain relief method such as epidural and/or opioids. "Nitrous oxide is a useful, safe option for labor analgesia in the United States. And for some laboring mothers, that's all the pain relief they need. Understanding predictors of conversion from inhaled nitrous oxide to other forms of analgesia may assist providers in their discussions with women about pain relief options during labor," said lead author and Associate Professor with the University of Colorado College of Nursing Priscilla M. Nodine, PhD, CNM.

The reason most often cited (96%) for converting from N₂O to an alternative therapy was inadequate pain relief. The odds of conversion from N₂O increased approximately 3-fold when labor was augmented with oxytocin and when labor was induced. Also, those who had a history of cesarean section and experienced labor post-cesarean had more than a 6-fold increased odds of conversion to neuraxial analgesia or epidural. The odds of conversion to

neuraxial analgesia decreased by 63% for individuals who had given birth previously relative to those who were giving birth for the first time.

Approximately 4 million women in the United States give birth each year, and for many, coping with labor is a significant concern. Epidurals and spinal blocks, also known as neuraxial analgesia, are the most frequently used pain management tools in the United States, with the main alternative being systemic opioids, which can be associated with both maternal and fetal adverse effects. Recently reintroduced as a pain relief option during labor in the United States, N₂O has a long history of use in many developed nations and is increasingly available in the US. “While there is a fair body of anecdotal evidence of safety and effectiveness for how nitrous oxide affects pain during labor, few systematic analyses of outcomes are available from US-based cohorts,” said Nodine.

About the University of Colorado Anschutz Medical Campus

The University of Colorado Anschutz Medical Campus is a world-class medical destination at the forefront of transformative science, medicine, education, and patient care. The campus encompasses the University of Colorado health professional schools, more than 60 centers and institutes, and two nationally ranked hospitals that treat more than 2 million adult and pediatric patients each year. Innovative, interconnected and highly collaborative, together we deliver life-changing treatments, patient care, professional training, and conduct world-renowned research powered by more than \$550 million in research awards. For more information, visit www.cuanschutz.edu.
